Fire and Ice: A Soot Removal Technique Using Dry Ice Blasting

By Randy Silverman

To say that for destruction ice
Is also great
And would suffice
—*Robert Frost* [1]

A WELDER'S SPARK TOUCHED off the attic fire in the Sevier County Recorders Office in Richfield, Utah on May 2, 2006, igniting a blaze that ripped through the crawl space consuming the building's paper-backed insulation. The fuel readily spent, the fire burned itself out 15 minutes later, sparing the structure but coating everything below the rafters with fine, powdery soot.

This carbonaceous residue filtered down through the ceiling tiles settling on everything in the offices below including the historic courthouse record books stored horizontally on metal rolling shelves within the vault. About 300 nineteenth and twentieth century full-leather spring-back stationers' bindings, many covered in protective white canvas jackets, were untouched by the fire but impregnated with a layer of soot and reeked of smoke.

The Problem

Among U.S. commercial disaster firms, the current standard for removing soot's residue from books is to wipe down the covers with a "chemical," or natural rubber sponge,[2] and then "ozonate" the books to eliminate the residual smoky odor. This approach leaves much to be desired. While the sponge traps much of the fine, carbon-laden particulate in its tan, rubbery surface, it also quickly fills with residue. Recovery workers must constantly rotate their sponges to

Among U.S. commercial disaster firms, the current standard for removing soot's residue from books is to wipe down the covers with a "chemical," or natural rubber sponge, and then "ozonate" the books to eliminate the residual smoky odor.

> *Soot's fine powder coats every exposed surface, penetrating even the tiniest crevices and crannies, anchoring the carbon with oily tars where it lands.*

expose unused areas to the grime and discard spent sponges as they are not readily cleaned. The wiping process forces some of the fine, dark soot particles back into the interstices of the material being cleaned, especially when that surface is as porous as the open weave of canvas book jackets.

Trapped soot becomes more intractable with time as the polymerized and dehydrogenized byproducts of the fire chemically bond to their surroundings.[3] The friction of wiping also causes some portion of the sponge's soft rubber to transfer to the book's surface, trading one unstable residue for another.[4] Finally, exposing "cleaned" books to ozone to reduce the residual smoke odor causes further degradation. A strong oxidizer, ozone aggressively breaks down paper, cloth, leather and adhesives while it decomposes the organic components of the smoke—a highly undesirable tradeoff for books of historic significance mandated by law to be maintained in perpetuity.

In short, soot is an extremely tenacious material to remove. Unlike dust, it is a solid/liquid residue composed of carbon suspended in an oily foundation of partially consumed combustion byproducts. The carbon within these tar droplets is so fine that it is readily dispersed by the "pressure and buoyancy created by the heat of the fire" and aerodynamic conditions such as "stack effect, wind pressures, the building geometry and its barriers (such as walls and floors), and ventilation practices."[5] Soot's fine powder coats every exposed surface, penetrating even the tiniest crevices and crannies, anchoring the carbon with oily tars where it lands. Removal attempts by wiping, even with an absorbent, fleshy material such as a natural rubber sponge, smears whatever soot does not bond to the sponge, compressing and embedding the diminutive, greasy specks further into the surface and making them more difficult to remove. As soot ages, it chemically cross-links to the material it is in contact with, making immediate cleanup the optimal course of choice.

An interior office with evidence of smoke damage on the walls. *Photo credit: Randy Silverman*

Vacuuming with a HEPA filter in tandem with manual wiping can help, but alone it is actually less effective than wiping with an absorbent material. In the 1997 Saskatchewan Museum fire, Spafford-Ricci and Graham report the soot removal protocol used for book cleaning included an initial vacuuming of the book's binding, followed by a separate vacuuming of the text block. Care was taken not to touch the surface of the books with the vacuum's nozzle as this contact would push soot into the woven fabric of the bookbindings. After vacuuming, the second phase of this cleanup included mechanically wiping the book's surface with rubber sponges or Webril® Wipes (a nonwoven 100% cotton pad used in the printing industry for non-abrasive cleaning of printing plates).[6]

Eliminating residual smoke odor from objects following soot removal is the next problem. In addition to spraying scents to mask the odor, three approaches predominate within the fire recovery industry: chemical deodorizing, thermal deodorizing and ozone treatment. Unfortunately, all have serious drawbacks when dealing with cultural heritage material.

Record book storage vault with metal roller shelving; a temporary positive air ventilation system is set up to help with soot extraction. *Photo credit: Randy Silverman*

Chemical deodorizing eliminates odors through a chemical reaction occurring when the chemical fumes of the product come into contact with smoke residue.

Chemical deodorizing eliminates odors through a chemical reaction occurring when the chemical fumes of the product come into contact with smoke residue. These deodorizers come in a wide range of extremely pungent fragrances designed to "purify" air spaces ranging in size from 1,000-20,000 cubic feet. The long-term effects on cultural property of these proprietary formulations have not been analyzed. More broadly, however, harmful effects from gaseous pollutants—particularly sulphur dioxide (SO_2), oxides of nitrogen (NO_X) and ozone (O_3)—have been well documented with paper, leather, textiles, dyes, pigments, inks, adhesives and photographic film.[7] Introduction of gaseous chemicals for deodorizing purposes is not recommended until their long-term effects can be tested.

Thermal oxidation deodorizing is a second approach used to eliminate volatile organic compounds (VOCs) from the ambient air. Essentially, the system is an afterburner that draws workplace air through a combustion chamber where VOCs are incinerated.[8] Mostly used in industrial settings to deal with gaseous byproducts from petrochemicals, printing, paint, food, sewage and waste treatment, application of this technology to reduce smoke odors from heritage materials has not yet, to my knowledge, been attempted.

Finally, ozone is commonly used to treat smoke odors in affected household and office objects. This treatment includes creating copious amounts of O_3 with an electric ozone generator and sequestering the smoke-damaged material in a confined space with the gas. Unfortunately, while O_3 eliminates smoke odors, in high concentrations O_3 is both harmful to human health[9] and an aggressive oxidizer known to harm a wide range of cultural heritage materials, as noted above.[10] Hence, despite its common use for less significant objects, O_3 should be avoided.

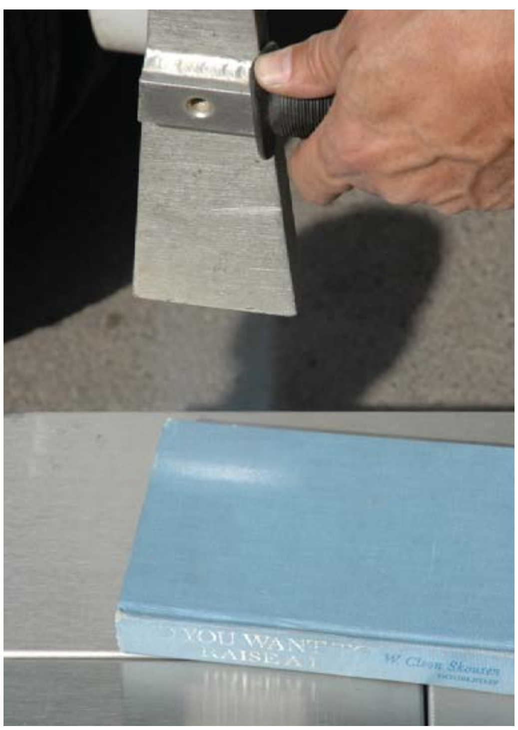
At present, the only safe approach to remove smoke odors from cultural material is to isolate objects in a room with an operating air purification system containing activated carbon, zeolite and/or potassium permanganate filtration. Continuously re-circulating filtered air past the objects will gradually reduce smoke's lingering odor if the material can be well exposed to the air flow. An inex-

In the aftermath of the Sevier County Recorders Office fire, a non-damaging alternative to the current cleaning options seemed desirable.

pensive alternative is to place small amounts of material in relatively airtight enclosures (such as a large, sealed plastic garbage bag) in close proximity to large quantities of exposed baking soda. Either approach may take two to three months to work with the key being to expose the impacted material to the absorbent media. Michael Trinkley reports, "Records which survived the 1906 San Francisco fire and are today in the National Archives still smell strongly of smoke—over 90 years later,"[11] a condition possibly exacerbated by the lack of air exchange.

Sevier County

In the aftermath of the Sevier County Recorders Office fire, a non-damaging alternative to the current cleaning options seemed desirable. Invited by the responsible commercial recovery company to serve as a consultant,[12] I suggested dry ice blasting as an interesting possibility. Dry ice blasting has proven its utility in a variety of industrial applications over the past decade



First test sample; a late twentieth century publishers' binding. Dry ice blasting adequately cleaned surface grime but if the focus of the blast was prolonged, gold stamping and pigment from the publishers' cloth were removed.
Photo credit: Randy Silverman

including dispatching paint from decorative metalwork; cleaning dirt from brick, granite, marble, onyx or other stone materials; stripping built-up wet or dry ink from printing presses; removing fused dust from electrical turbines, generator windings and transformers; and remediating mold from building interiors.[13] The system is portable and can be powered by an electric generator, adding significantly to its merits since the County Recorder would not permit the damaged books to leave the Recorders Office.

The process works by shaving solid blocks of dry ice (frozen CO_2) into granules ranging in size from the diameter of sugar to the shape of rice, depending upon the application. These granules are propelled in a compressed air stream of 30-300 PSI against the surface to be cleaned. Dry ice blasting is considered completely non-abrasive when used on surfaces harder than frozen CO_2, but can be used to "antique" wooden siding by differentially abrading the softer, pithy wood and leaving the grain. Frozen CO_2 pellets emerge from the nozzle at -78°C, dramatically lowering the surface temperature of the media being cleaned and causing incremental shrinkage. This contraction occurs simultaneously as the CO_2 sublimates to its gas phase, expanding approximately 80-800 times its original size. These multiple forces—contraction due to cold, turbulence caused by rapid sublimation and pressure from the compressed air stream—occur simultaneously. As the minute dry ice particles penetrate the interstices of the media being cleaned, the CO_2 sublimates leaving only "dirt" as the residual byproduct.

In preparation to attempting soot removal from Sevier County's record books using dry ice blasting, a couple of expendable modern publishers' bindings were tested. With the dry ice crystals ground sugar-fine, the PSI set to a minimum (30 PSI) and the compressed air nozzle held far enough from the books to prevent abrasion (15-18 inches), a local applicator[14] expertly cleaned these mock ups while

Second test sample; cleaning results from a lightly soot damaged 20th century record book covered in a protective white canvas jacket. The area of the jacket left of the number "73" and below the word "Deed" was wiped with a natural rubber sponge; right of the number "73" and below the word "Deed" was vacuumed with a HEPA vac; and, the area above the words "Deed Record" was dry ice blasted. *Photo credit: Randy Silverman*

An 18th century full-leather record book sitting on the Alpheus Precision Series™ Model T-2 dry ice blasting machine as it is refilled with block dry ice. *Photo credit: Randy Silverman*

I monitored the effect. The applicator played the machine's[15] spray of CO_2 granules in a steady sweep across the bindings, his experience essential to preventing damage. The technique worked flawlessly, but we discovered that too long a focus on one spot or allowing too little distance between the nozzle and book's surface, could remove dye from the cloth or gold foil stamping from the cover. We also found that older, hand tooling (both hand stamping and decorative lines run with a roll) presented no problem in the cleaning, suggesting that modern titling on mass market books is far more friable than earlier handwork. Similarly, directing the dry ice nozzle directly at the edges of the text could abrade the paper surface slightly, so the situation was remedied by focusing the nozzle's aim specifically at the board edge so only the peripheral dry ice spray played over the fore-edge, head and tail. By firmly clamping the text closed and minimizing direct pressure to the paper edges the text was undamaged by the cleaning process.

We then compared dry ice blasting with two other forms of soot removal using actual record books; wiping down part of a book with a natural rubber sponge and vacuuming another section with a HEPA filter. The rubber sponge proved reasonably effective although it left some visible soot residue. The HEPA-vacuuming proved far less effective than the sponge, underscoring the bonding strength of the soot, even a week after the fire. Dry ice blasting proved the most effective of the three methods and caused no detectable abrasion. In addition to removing

Frozen CO_2, which comes from liquid CO_2, used in soot removal is different than CO_2, which is produced as a by-product of another process. It is not excess CO_2 but CO_2 that has been reclaimed or recycled from CO_2 already existing in the environment. Dry ice blasting, an environmentally conscious way to use existing CO_2 to our advantage, is environmentally friendly and not environmentally damaging.

Dry ice blasting pellets is environmentally friendly and contains no secondary contaminants such as solvents or grit media. They are non-toxic, non-hazardous creating advantages to the environment, your employees, and production facility:

- No secondary waste
- Safe for the environment
- Safe for employees
- Safe for end products
- Safe for equipment

We then compared dry ice blasting with two other forms of soot removal using actual record books; wiping down part of a book with a natural rubber sponge and vacuuming another section with a HEPA filter.

While dry ice blasting has been successfully used for mold remediation on building surfaces, its application to removing mold from damaged bindings has yet to be investigated.

the soot, the cleaning eliminated years of embedded hand grease as well as a piece of pressure sensitive tape along with the discolored adhesive residue beneath it. As a further test, each cleaned object was sequestered overnight in a sealed box to determine how much residual smoke odor remained. Again, dry ice blasting surpassed the other cleaning methods.

The technique also proved to be far faster than wiping down the books with rubber sponges. The canvas-covered bindings took longer to clean than books with exposed leather, but on average, six books were dry ice blasted per hour (50 hours total). Jayrene Nielsen, the County Clerk, expressed her amazement at the end result. She claimed the books had never looked so clean. While building repairs progressed, the commercial recovery company, leery of a slight residual smoke odor, packaged the cleaned volumes for storage in boxes containing a chemical deodorizer. In direct discussion about this with the County Clerk, Ms. Nielsen agreed to remove the deodorizers from the boxes, claiming she actually preferred the smell of smoke to the noxious deodorant! She also believed the smoke odor was rapidly dissipating as the books aired out.

As with any new conservation technique, dry ice blasting will surely prove to have its limitations. Based on the excellent results at Sevier County, however, it appears the technique has great promise for addressing certain problems and should be considered as a viable option as the situation demands. Additionally, further safeguards or modifications to the approach described herein may be warranted. Great care should be exercised, for example, when testing dry ice blasting's effectiveness for removing soot from rare books, as the age and variability of the material involved might well present numerous challenges. While dry ice blasting has been successfully used for mold remediation on building surfaces, its application to removing mold from damaged bindings has yet to be investigated. Dry ice blasting seems to offer much promise and additional reports and testing arising from future applications of the technology are encouraged.

CoLibrì Book Cover System

CoLibrì Pocket Machine

Demo Trolley

Leonardo Machine

COLIBRÌ IS THE FIRST automated system that covers the entire book with dust jacket without any adhesive quickly and automatically. The process takes less than 30 seconds and consolidates a library's entire book covering operation into a single process. The special polyethylene covers are tailor fit to protect all edges yet, can be removed or replaced without damaging the endsheet of the book, the book cover or the dust jacket. Your book's cover is completely encapsulated and protected.

CoLibrì Book Covering System has a sleek look, is compact and can fold for travel. The quick application saves time, protects your book with a perfectly tailored cover and improves the life span of your books. The CoLibrì Pocket Machine covers books using the mini, standard and big covers. The new Leonardo Machine utilizes less space and accommodates book sizes in the mini and standard size range. Both will protect soft-cover books, jacketed hard bound books or leather bindings with red rot.

Covers are available in three sizes to accommodate a wide range of book sizes. Pouches for documents, certificates, photographs and objects are also available. Using the same covers for hard covers, paperbacks, magazines and jacket covers can minimize your cover material stock levels.

For labs that use the CoLibrì Book Covering System continually, we now offer a handle bar that connects the two handles for one-handed use and better production efficiency. A demo trolley is also available for machines that are moved frequently to other locations.

Specifications

CoLibrì Pocket & Leonardo Machines

- Semi-automatic, lightweight trimming and welding book covering machine.
- Simply and cleanly products perfectly squared covering that are immediately ready for use.
- Takes 20-30 seconds to obtain a custom-fitted, durable and protective covering that perfectly adheres to the book without glue.
- Trims and welds covers squarely.

CoLibrì Pocket

- Uses standard, mini and big size covers.
- Maximum welding length: 24 3/4".
- Overall Dimensions: 26" x 16" x 5".

CoLibrì Leonardo

- Uses the standard and mini size covers only.
- Maximum welding length: 19.7".
- Overall Dimensions: 22" x 16 3/16" x 3 1/2".

Covers

- 100% transparent polyethylene.
- Non-toxic, odorless and water resistant.
- Specially calendered for softness.
- Protective cover clings to the book without adhesives.
- Does not alter the book cover and may be removed and replaced at any time.
- Three formats to easily and quickly cover books.

Protect: Books, publications, photos, maps architectural plans and objects.

For more information or to arrange a free CoLibrì Cover sample on your book contact us at 800-526-5640 or custserv@archival.com.
